# **Storing and Accessing Data row**

Lesson 02: Primary Index Mechanics

# Storing and Accessing Data Rows

#### How Does Teradata Store Rows?

- Teradata uses hash partitioning and distribution to randomly and evenly distribute data
- > across all AMPs.
- ➤The rows of every table are distributed among all AMPs and ideally will be evenly distributed among all AMPs.
- ➤ Each AMP is responsible for a subset of the rows of each table. Evenly distributed tables result in evenly distributed workloads. The data is not placed in any particular order

The benefits of unordered data include:

☐ No maintenance needed to preserve order, and
☐ It is independent of any query being submitted.

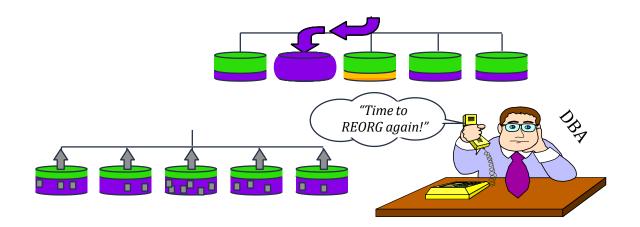

The benefits of automatic data placement :

☐ Distribution is the same regardless of data
☐ Distribution is based on row content, not data

#### How do other databases Store Rows

- Many use range distribution Creates intensive maintenance for DBA DBA's must consider:
  - How to partition the data
  - How large to make the partitions Where is there data contention How are users accessing the data

Placing all data into a single partition creates bottlenecks for all queries against that data.

Teradata DBAs never need to do costly reorganizations!

#### **Primary Indexes**

- ➤ The mechanism used to assign a row to an AMP
- ➤ A table must have a Primary Index
- ➤ The Primary Index cannot be changed

UP UPI's guarantee even data distribution and eliminate duplicate row checking.
$\Box$ If the index choice of column(s) is unique, we call this a <i>UPI</i> (Unique Primary
Index).
$\hfill\square$ A UPI choice will result in even distribution of the rows of the table across all AMPs.
$\square$ If the index choice of column(s) isn't unique, we call this a <i>NUPI</i> (Non-Unique Primary Index).
☐ A NUPI choice will result in even distribution of the rows of the table proportional
to the degree of uniqueness of the index.

#### Creating a Primary Index

- >A Primary Index is defined at table creation.
- > It may consist of a single column or a combination of up to 16 columns.

NUPI

```
CREATE TABLE sample_2

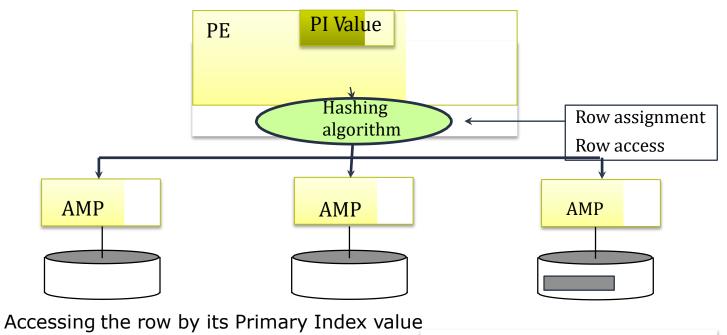

(col_x
INT
,col_y INT
,col_z INT)

PRIMARY INDEX (col_x);
```

Note: Changing the Primary Index requires dropping and recreating the table.

#### Primary Index Values

- The value of the Primary Index for a specific row determines its AMP assignment.
- >This is done using the hashing algorithm.

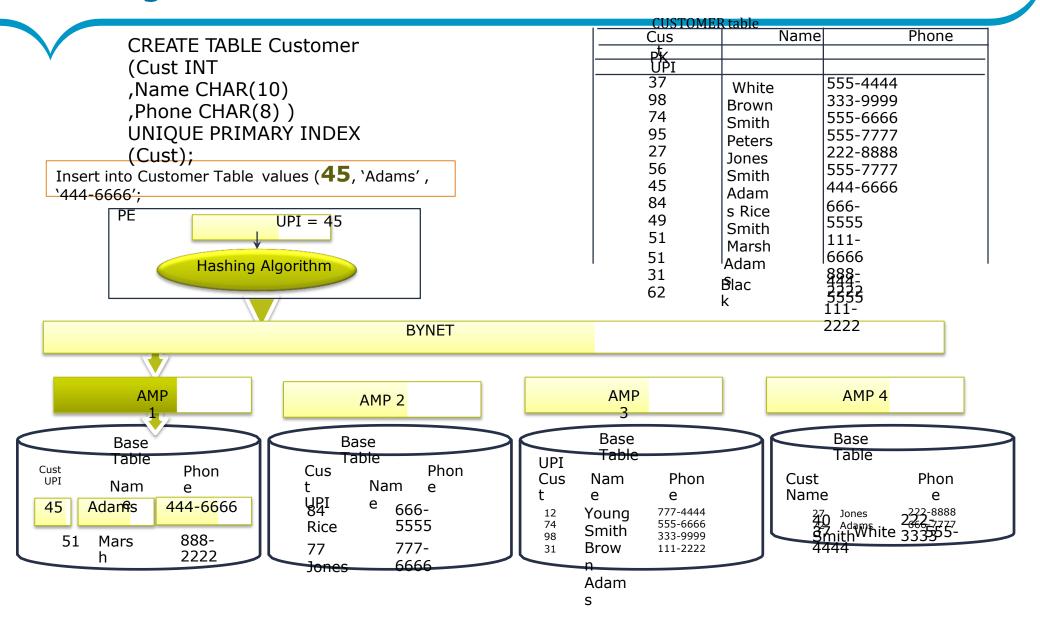

is:

- Always a *one-AMP* operation
- The most efficient way to access a row

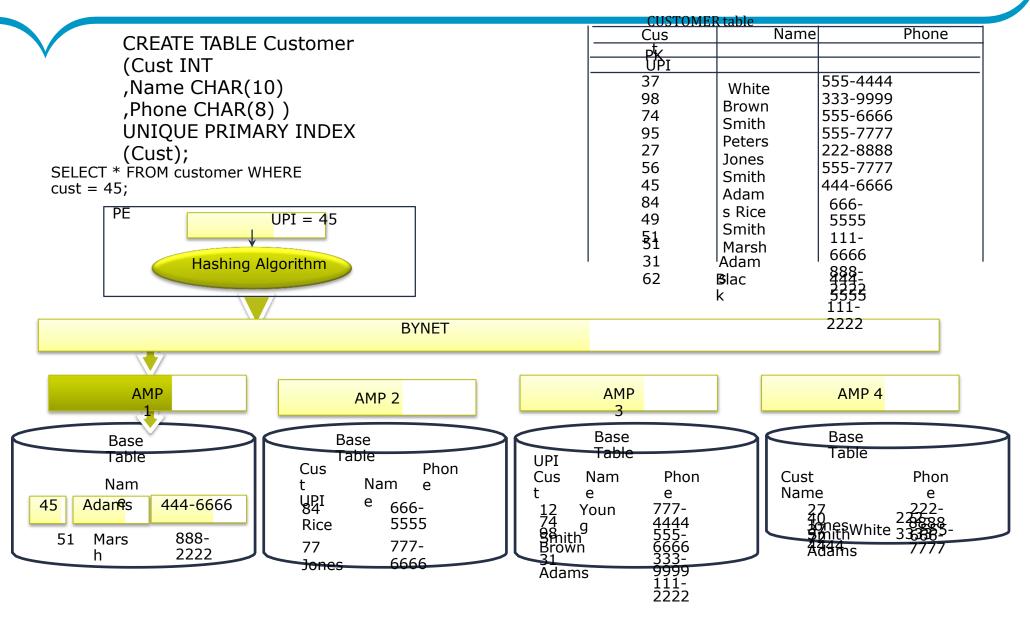

Other table access techniques:

- Secondary index access
- Full table scans

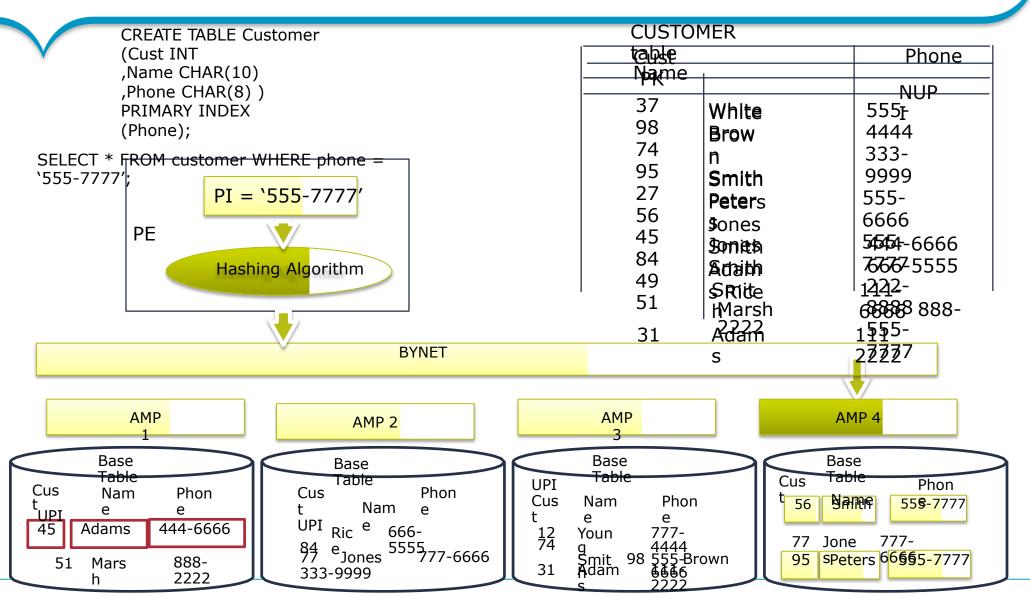

#### Adding New Row

#### Accessing Via a Unique Primary Index

## Accessing Via a Non Unique Primary Index

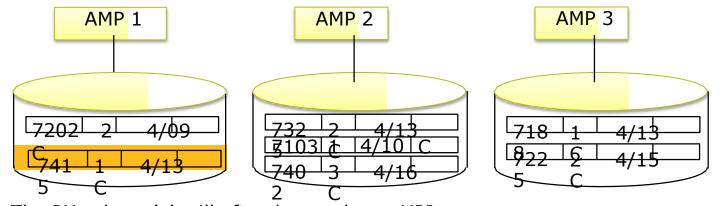

Indexes are conceptually different from keys: ☐ A PK is a relational modeling conve ☐ uniquely identified. A PI is a Teradata convention which and accessed.		
Primary Key		Primary Physical mec <b>fradex</b> n for access and storage
Logical concept of data  modeling		Each table must have exactly one 16-column limit
Teradata doesn't need to recognize		Defined in CREATE TABLE statement
No limit on column numbers		May be unique or non-unique
Documented in data model (Optional in CREATE TAE	BLE)	Used to place and locate each row on an AMP
Must be unique		Values may be changed (Del+ Ins)
Uniquely identifies each row		May be NULL
Values should not change May not be NULL—requires a		Defines most efficient access path
value		Chosen for physical performance
Does not imply an access path		
Chosen. $\square$ A significant percentage of tables may us PI.	se the same	columns for both the PK and the
☐ A well-designed database will use a PI th	at is differen	it from the PK for some tables.

OW	Distri	bution	Using	an	UPI

Order Number	Customer Number	Order Date	Order Status
PK			
UPI			
7325 7324 7415 7103 7225 7384 7402 7188 7202	2 3 1 1 2 1 3 1 2	4/13 4/13 4/13 4/10 4/15 4/12 4/16 4/13 4/09	0 0 0 0 0 0 0 0 0 0

AMP 4

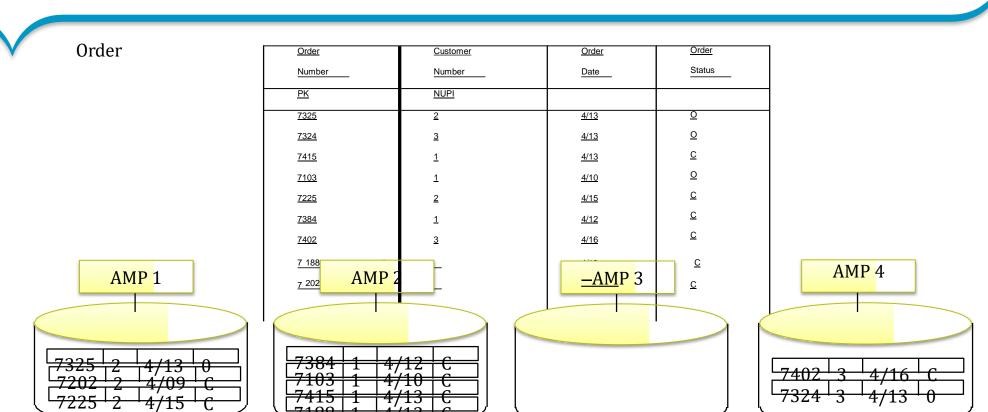

The PK column(s) will often be used as a UPI.

PI values for Order\_Number are known to be unique (it's a PK).

- ☐ Teradata will distribute different index values evenly across
- □all AMPs.

Resulting row distribution among AMPs is uniform.

#### Row Distribution Using an NUPI

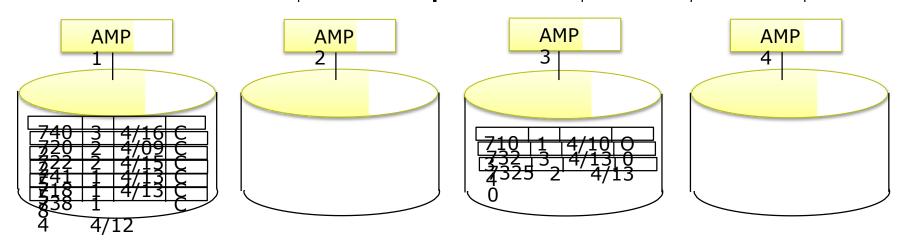

- Customer\_Number may be the preferred access column for ORDER table, thus a good index
- candidate.
- Values for Customer\_Number are non-unique and therefore a NUPI.
   Rows with the same PI value distribute to the same AMP causing row distribution to be less uniform or skewed.

### Row Distribution Using a Highly Non Unique Index

_		
(1)	rd	Or.
$\mathbf{C}$	ıu	CI

Status
NUPI
0 0
СО
CC
CC
С

- Values for Order\_Status are highly non-unique, and therefore, it is a
- NUPI.
- Only two values exist, so only two AMPs will ever be used for this
- table.
- This table will not perform well in parallel operations.
  - Highly non-unique columns are poor PI choices.
  - The degree of uniqueness is critical to efficiency.

# **Secondary Indexes**

#### Secondary Indexes

- A secondary index is an alternate path to the rows of a table.
- A table can have from 0 to 32 secondary indexes. Secondary indexes:
  - Do not affect table distribution.
  - Add overhead, both in terms of disk space and maintenance.
  - May be added or dropped dynamically as needed. Are chosen to improve table performance.

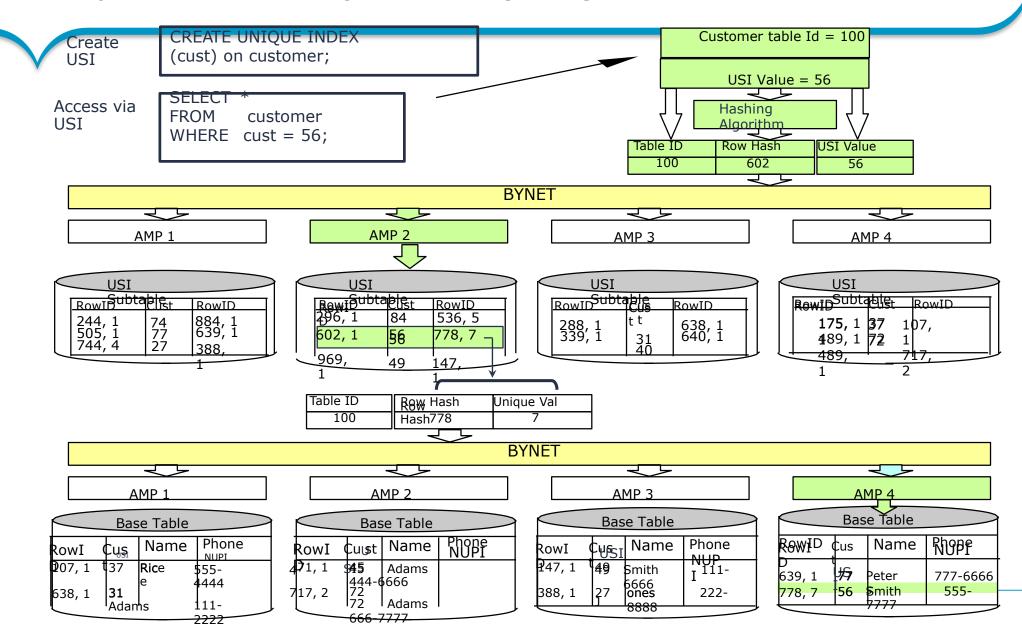

There are three general ways to access a table:			
☐ Primary index access	(one-AMP access)		
☐ Secondary index access	(two-or all-AMP access)		
☐ Full Table Scan	(all-AMP access)		

#### Choosing a Secondary Index

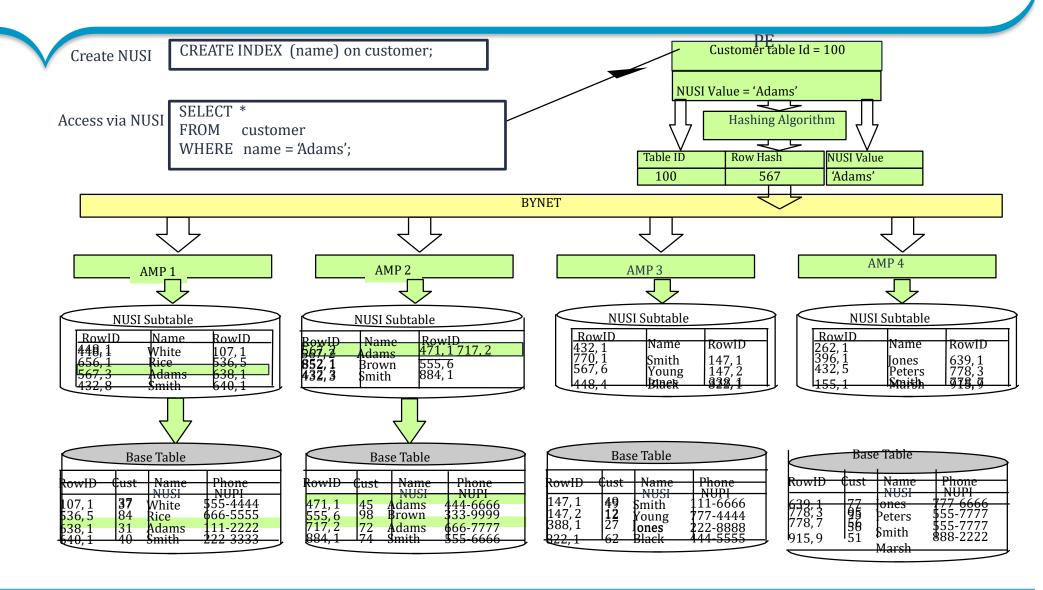

A secondary index may be ->At table (CREATE -> Following table creation (CREATE defined: NDEX) up to 16 > columns US If the index choice of column(s) is unique, it is called a USI (unique secondary index). Accessing a row via a USI typically requires 2 AMPs. NUS If the index choice of column(s) is non-unique, it is called a NUSI (non-unique secondary index). Accessing a row via a NUSI requires all AMPs. US NUS CREATE INDEX (last-name) on **CREATE UNIQUE** employee INDEX <del>(employee-number) n</del> employee employee Note: Secondary indexes cause an internal sub-table to be built. Dropping the index causes the sub-table to be deleted.

#### Unique Secondary Index (USI) Access

#### Non-Unique Secondary Index (NUSI) Access

## Comparison of Primary and Secondary Indexes

Index Feature	Primary	Secondary
Required?	Yes	No
Number per Table	1	0-32
Max Number of Columns	16	16
Unique or Non-Unique?	Both	Both
Affects Row Distribution	Yes	No
Created/Dropped Dynamically	No	Yes
Improves Access	Yes	Yes
Multiple Data Types	Yes	Yes
Separate Physical Structure	None	Sub-table
Extra Processing Overhead	No	Yes

#### Full - Table Scans

- > Every row of the table must be read.
- All AMPs scan their portion of the table in parallel. Primary Index choice affects FTS performance.
- > Full-table scans typically occur when either:
  - The index columns are not used in the query
  - An index is used in a non-equality test
  - A range of values is specified for the primary index

#### **CUSTOMER**

Cust_ID	Cust_Name	Cust_Phone
USI	NUSI	NUPI

#### Examples of Full-Table

#### Scans:

```
SELECT * FROM customer WHERE Cust_Phone LIKE `524-_ _ _ _';
SELECT * FROM customer WHERE Cust_Name <> `Davis';
SELECT * FROM customer WHERE Cust_ID > 1000;
```
